

INTRODUCTION

An ecommerce database is a crucial component of any successful online business, providing a structured and organized system for storing and managing essential data. The main purpose of an ecommerce database is to facilitate efficient and effective management of product information, customer data, and transactional information, thereby enabling seamless customer interactions and business operations.

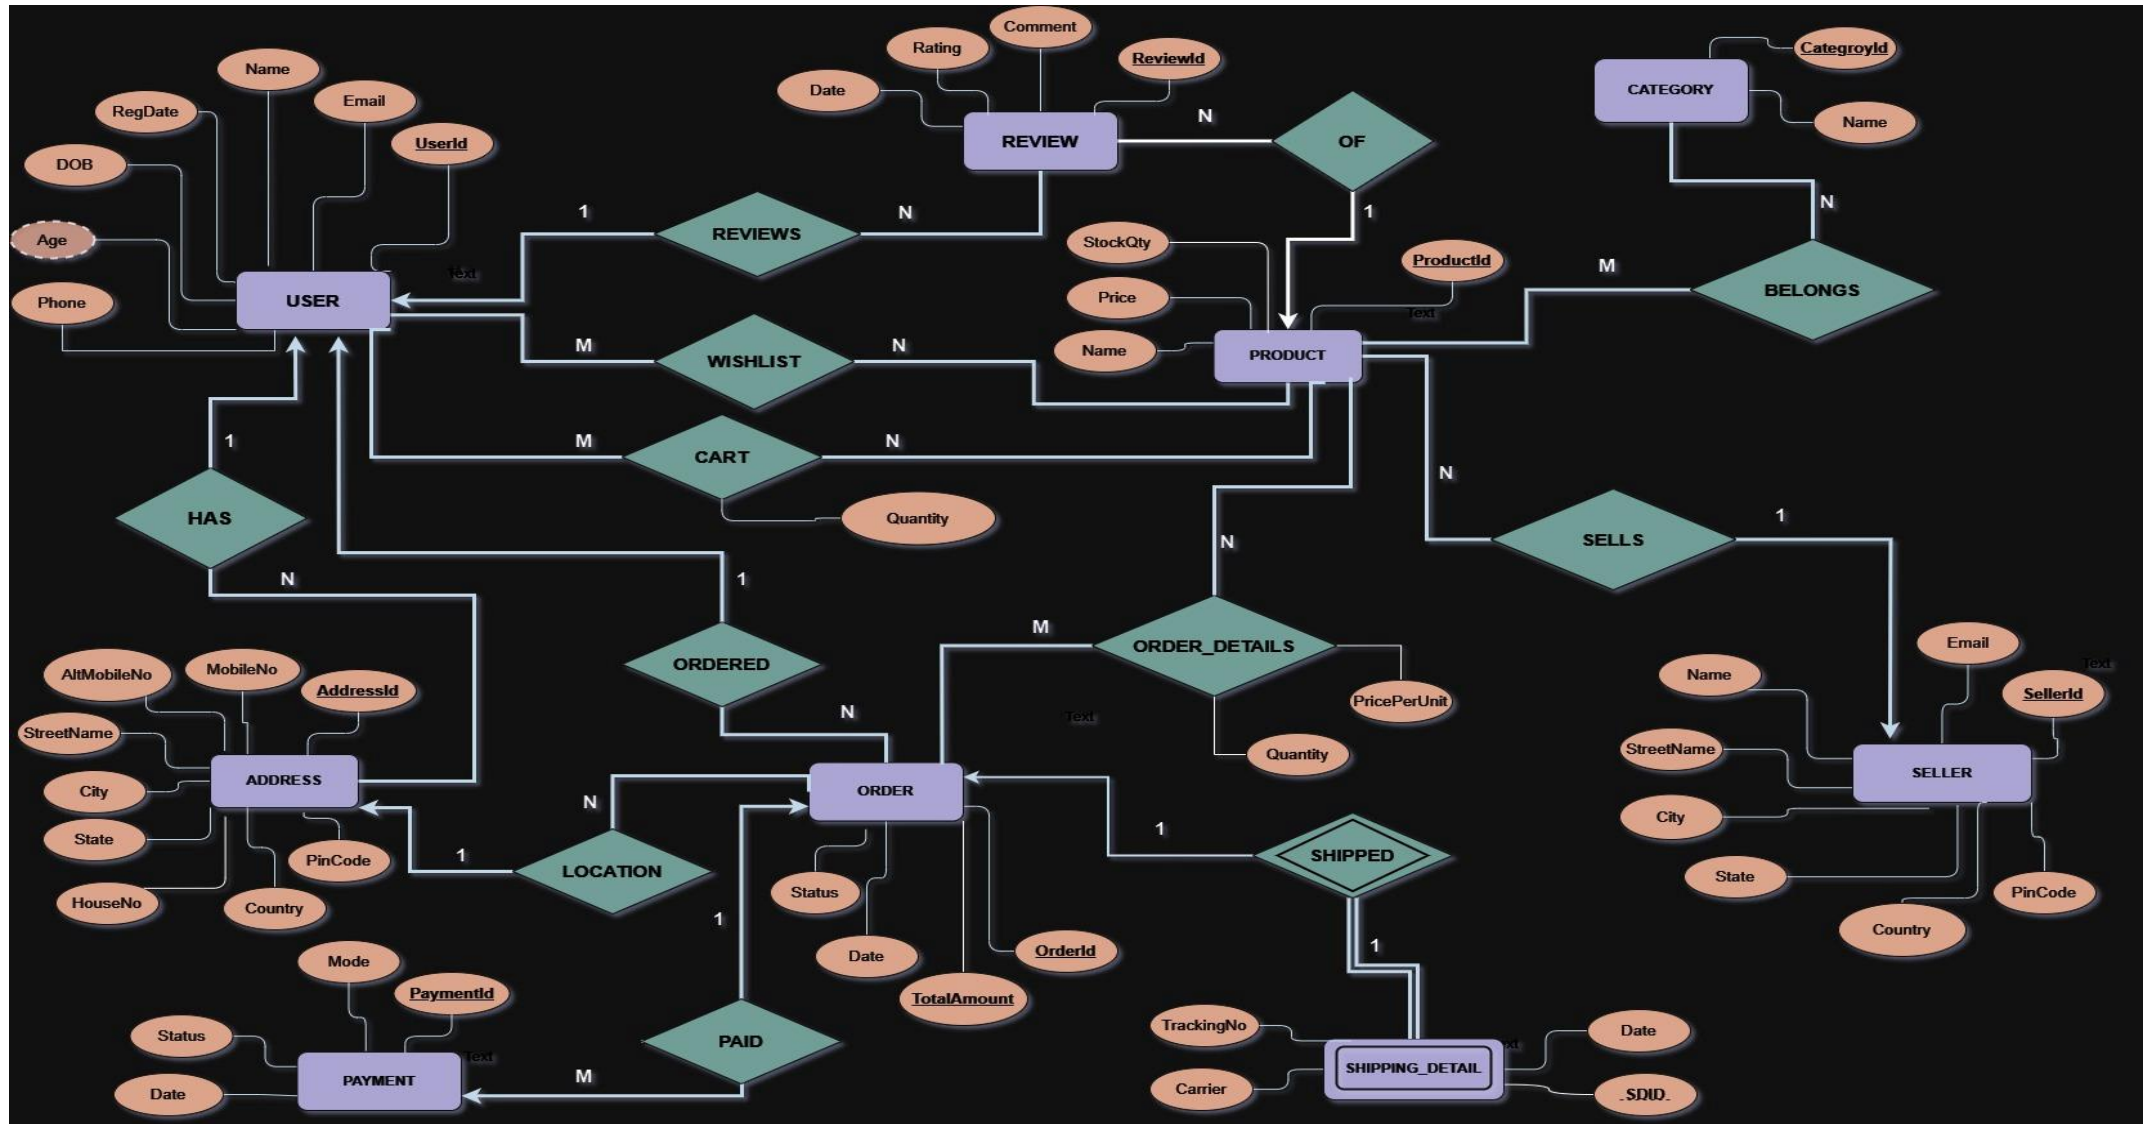

In today's booming e-commerce landscape, efficient data management is crucial. This project tackles that challenge by designing and building a robust database for an online store. We'll create a comprehensive schema to handle products, customers, orders, etc. By leveraging SQL, we'll enable efficient data retrieval and manipulation. This project lays the foundation for a fully functional e-commerce platform, giving us valuable insights into best practices for e-commerce database management.

We aim to design and implement an ecommerce database that can handle the complex data requirements of an online store. This includes organizing data in a coherent structure to keep track of inventories, updating product catalogs, and managing transactions.

ER MODEL ASSUMPTIONS AND KEY POINTS

1. User can have multiple addresses. User to address is one to many relationship.
2. Multiple users can review for same product and one user can review many products. User and review have many to many relationship.
3. Price of products may change later so Price at time of order is added to order details relation.
4. Order and Payment has one to one relationship.
5. User can have multiple orders, so user and order have one to many relationship.
6. A seller can sell many products, but each product can be sold by one seller.
7. One product can have many reviews, but each review is for one product.
8. One product belongs to one category, but one category can have many products.
